On June 23, 2001, at 8:33 PM UTC, 3:33 PM local time, a $M_w=8.3$ (USGS) earthquake occurred near the coast of south-central Peru along the subduction zone between the Nazca and South American tectonic plates. The districts of Arequipa, Moquegua, Tacna, and Ayacucho sustained losses (Figures 1 and 2). This initial reconnaissance report has been prepared by Eduardo Fierro of Wiss, Janney, Elstner Associates Inc. based on his field observations from June 28th to July 3rd.
The National Institute for Civil Defense of Peru reports 77 dead, 68 missing, 2,713 wounded, 213,430 people affected, 33,570 houses damaged, and 25,399 houses destroyed. A geographic breakdown of the losses is given above in Figure 2.

There have been dozens of strong aftershocks in the region (Figure 3).

To date, only one strong motion record of the main event has been recovered from a station in Moquegua. Two other instruments in the epicentral area apparently malfunctioned. Field surveys and local reports indicate that the duration of ground motion was relatively long (45-60 seconds) with peak ground accelerations ranging from approximately 0.10g near Arequipa to 0.30g near Moquegua. The southern coastline was affected by a tsunami following the main event; the coastal towns of Ocoña and Camana were particularly hard hit.
Observations from Locations Reporting Most of the Damage

AREQUIPA

The ground accelerations were apparently not very high in Arequipa, a city located about 120 miles inland from the epicenter of the main event. There are no ground motion records from Arequipa, apparently due to instrument malfunction. However, local people reported that the duration of motion was approximately one minute. Primarily historical buildings and older stone masonry structures sustained damage. An estimate of 0.10g appears reasonable for the peak ground acceleration in Arequipa based on observed damage patterns.

The city’s historic Cathedral of Arequipa sustained heavy damage, mainly due to the collapse of one of its towers. The cathedral is situated on the Plaza de Armas in Arequipa's historic center, a UNESCO World Heritage site. The cathedral, founded in 1612, was damaged by previous earthquakes and fire and was substantially rebuilt in the 19th century. Both towers of the cathedral were apparently damaged in previous earthquakes and rebuilt most recently in about 1940. This cathedral is the symbol of Arequipa and an important part of the architectural heritage of Peru.

A set of still photos extracted from a video recording taken during the earthquake shows part of the collapse sequence of the towers at the Cathedral of Arequipa (Figures 6 and 7, photos purchased by E. Fierro). Figures 8 to 13 show details of the damage, especially to the towers.

Figures 12 and 13. The precarious tower is supported by four 35 cm by 35 cm concrete columns and four steel rails. One of the steel rails buckled. Arches attached to the main structure were also damaged. (Photos by E. Fierro)
Many cathedrals and religious monuments sustained damage. The Convent of Santa Catalina, founded in 1579, was heavily damaged. Many traditional domed and vaulted structures were extensively damaged. One example of a lightly damaged vaulted ceiling in an historic home is shown in Figure 16. Many of the damaged older dwellings have roofs made with heavy blocks of low strength “sillar” (consolidated volcanic ash) supported by steel rails (Figure 17).

COASTLINE NEAR CAMANÁ AND OCOÑA

At least 50 landslides or rock falls were reported along the Pan-American Highway south of Camaná in La Bajada del Diablo (Figure 18). No warning signs were observed anywhere along the roadway. The major damage to the south of Camaná was caused by the tsunami induced by the main shock (Figures 19 to 23). Residents reported that within 20 minutes after the ground shaking, three waves around 4 meters high hit the coastline near Camaná (source: Reuters). However, this area is primarily used as a summer resort and since it is currently winter in Peru, most of the beachfront properties were unoccupied. The tsunami caused extensive property damage along 30 kilometers of the coastline and reportedly resulted in the loss of 15 to 20 lives.

Downtown Camaná suffered minor damage. Primarily adobe houses and some school buildings sustained structural damage. Most of the damage could be attributed to configuration problems such as soft stories or short-column effects. Figures 24 to 27 show typical damage to old school buildings. Both new and older schools with short column problems performed poorly. Schools designed using the most recent Peruvian code had isolation details between infill masonry walls and the concrete framing and avoided the short column failures. Figures 28 and 29 show an example of the most recent school construction; the school shown in these photos performed well.

OCOÑA

In Ocoña, a small city near the coast to the northwest of Camaná, mainly adobe houses sustained damage. Field observations indicate that the city experienced relatively low ground shaking.

Figures 30 and 31. Church in Ocoña built using very poor construction materials; both the mortar and brick were weak. Previously damaged and patched following earthquake 4 years ago. (Photos by E. Fierro)

SUMMARY

Initial surveys indicate that most damage occurred in areas to the east and southeast of the epicenter of the main event and that historic structures and old houses sustained the most severe damage. The coastline south of the epicenter was extensively damaged by the tsunami that followed the main shock. The intensity of ground shaking varied with a maximum peak ground acceleration of approximately 0.30g, and all reports indicate that the shaking continued for a long duration. Strong aftershocks are still occurring on a daily basis.
The Peruvian National Institute for Civil Defense reports that distribution of immediate relief material is ongoing as of July 5, 2001. The Peruvians may need long-term international financial and technical support for repair and rehabilitation of the damaged historic structures, which are an important part of our international cultural heritage.

ACKNOWLEDGEMENTS

All the photos and field observations in this report are by Eduardo Fierro from the San Francisco/Emeryville branch office of Wiss, Janney, Elstner Associates, Inc.(WJE). Mr. Fierro is originally from Callao, Peru. This report was assembled and edited by Ayhan Irfanoglu and Cynthia Perry, also of WJE, based on photos and text emailed from Peru by Eduardo Fierro. Mr. Fierro can be contacted at mailto:efa@wje.com.

Mr. Fierro would like to gratefully acknowledge the assistance of local officials and members of the engineering community in Peru in providing access, accommodations, and information. In particular, he would like to thank Jorge Ojeda, Executive Director of Autodemas; José Tong, Dean of the Colegio de Ingenieros de Lima; Daniel Torrealva, Universidad Catolica del Peru; Alejandro Muñoz, Universidad Catolica del Peru; Javier Pique, Universidad Nacional de Ingenieria; and Adolpho Gonzalez, Colegio de Ingenieros de Tacna. Names of other individuals who provided assistance will be included in the final version of this reconnaissance report.
